What is machine learning?

- **Artificial Intelligence (AI)** is the broad field that aims to create machines capable of intelligent behavior.
- **Machine Learning (ML)** is a subset of AI that focuses on algorithms that learn from data.
- **Artificial Neural Networks (ANNs)** are models inspired by the human brain, forming the foundation of many ML systems.
- **Deep Learning (DL)** refers to neural networks with many layers, capable of learning complex patterns in large datasets.

Supervised vs. Unsupervised Learning

Supervised Learning

- Learns a function from **labeled data**:
 $\{(x_1, y_1), \dots, (x_n, y_n)\}$
- Goal: minimize prediction error
$$\min_{\theta} \sum_{i=1}^n L(f(x_i; \theta), y_i)$$
- Tasks:
 - Classification (e.g., phase = WC or binder)
 - Regression (e.g., hardness prediction)

Unsupervised Learning

- Learns from **unlabeled data**:
 $\{x_1, x_2, \dots, x_n\}$
- Goal: find hidden structure (clusters, manifolds)
- Methods:
 - Clustering (e.g., K-means, GMM)
 - Dimensionality reduction (e.g., PCA, t-SNE)

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

6

Training, Validation, and Testing: Managing Your Dataset

- Training set: Used to learn the model parameters
- Validation set: Used to tune hyperparameters and prevent overfitting
- Test set: Used only at the end to evaluate generalization

- Training $\approx 60\% - 70\%$

- Validation $\approx 15\% - 20\%$

- Test $\approx 15\% - 20\%$

Cross-validation (e.g. K-fold):
Rotate training/validation sets across K partitions

7

7

Deep Learning: Overview

- Deep learning is a subfield of machine learning based on **artificial neural networks (ANNs)** with many layers. It enables the **automatic extraction of features** from raw, high-dimensional data (e.g., images, signals, curves).

- A deep model learns a **composition of functions**:

$$f(x) = f_L(f_{\{L-1\}}(\dots f_1(x)))$$

- where each layer f_l is a non-linear transformation with trainable parameters.

Artificial Neural Network (ANN)

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

10 

Underfitting / Overfitting

➤ **Underfitting:** Model too simple, fails to capture the structure of the data

➤ **Optimal fit:** Model generalizes well, captures patterns without memorizing noise

➤ **Overfitting:** Model is too complex, fits the training data perfectly but performs poorly on unseen data

➤ Training error:

$$L_{train} = \frac{1}{n} \sum_i (f(x_i) - y_i)^2$$

➤ Generalization gap:

$$Gap = L_{val} - L_{train}$$

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

11

11

Generalization: The Core Goal

- In supervised learning, we don't care about performance on the training set. We care about **how well the model performs on unseen data.**

- This is the **generalization error**:

$$\varepsilon_{gen} = \mathbb{E}_{x,y \sim \mathcal{D}_{test}} [L(f(x), y)]$$

- A model that memorizes data (overfits) is not generalizing. A model that underfits never captures the signal.

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

12

12

Interpreting Model Predictions Feature by Feature

- SHAP (SHapley Additive exPlanations) assigns each feature an importance value for a specific prediction. It explains how much each feature **contributes to the prediction's accuracy** relative to a baseline.

SHAP Summary Plot (global explanation)

Beeswarm plot:

Y-axis: features

X-axis: SHAP values

Color: feature value (low to high)

Shows which features matter globally and how they affect predictions

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

13

13

CNN (Convolutional Neural Networks)

- A CNN is a neural network architecture designed to process **grid-structured data** (e.g., images, 2D maps).
- It learns **spatial hierarchies of features** through layers of convolutions, pooling, and nonlinear activations.
- No need for manual feature engineering (useful for complexity)

Lee et al., ICML 2009 (DOI:10.1145/1553374.1553453), adapted from A.Amini

14

Main ML libraries in Python

1. Scikit-Learn

A simple and efficient tool for data mining and data analysis, built on NumPy, SciPy, and matplotlib.

• Features:

1. Easy-to-use interfaces for various machine learning algorithms.
2. Preprocessing tools and utilities.
3. Comprehensive documentation and active community support.

2. TensorFlow

Open-source library developed by Google for deep learning and neural networks.

Features:

1. Flexibility to build and train custom machine learning models.
2. Support for both CPU and GPU computing.
3. High-level APIs like Keras for easier model building.

3. PyTorch

An open-source deep learning framework developed by Facebook's AI Research lab, used for applications such as computer vision and natural language processing.

• Features:

1. Dynamic computation graphs for flexibility and speed.
2. Strong GPU acceleration support.
3. Integration with Python for easy and intuitive coding.

15

Seeing structure in high-dimensional data

Dimensionality reduction
(PCA, t-SNE, UMAP)

Run it: notebook 08
scan or click - Colab, no install

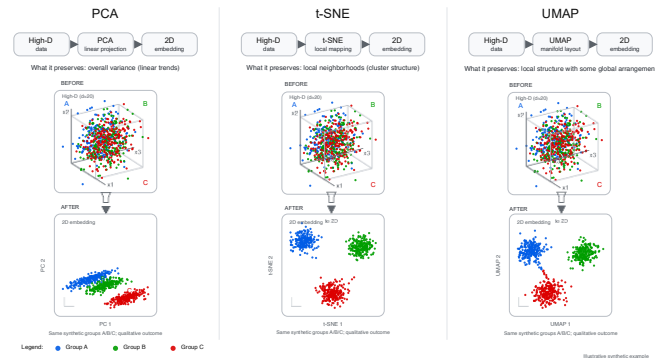

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

16

16

Seeing structure in high-dimensional data

- **PCA**: a linear rotation that keeps the directions of greatest variance; fast, but sees only linear structure
- **t-SNE**: nonlinear; places similar curves together by minimising the **KL divergence** (how far the 2-D neighbour-probabilities sit from the high-D ones). Clusters are meaningful; the gaps between them are not
- **UMAP**: nonlinear like t-SNE but faster, and keeps more of the global layout

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

17

17

The two pillars of unsupervised clustering

k-means partitions the indents into K groups, each summarised by a centroid (the mean H, E ... of its members), and iterates until the within-cluster scatter $\sum \|x_i - \mu_j\|^2$ stops shrinking. Fast and scalable to 10^5 indents, but it assumes round, equal-size clusters and depends on the starting seeds.

$$\text{Min} \sum_{j=1}^K \sum_{x_i \in C_j} \|x_i - \mu_j\|^2$$

k-medoids does the same, but each cluster centre is a real measured indent (a medoid), not an average. That makes it robust to outliers and usable with any distance metric: at higher computational cost.

$$\text{Min} \sum_{j=1}^K \sum_{x_i \in C_j} d(x_i, m_j)$$

Use k-medoids when the cluster centre must be a physically-measurable point: a representative nanoindentation test you can re-examine: or when robustness to outliers and non-Euclidean distances matters.

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

18

18

Supervised **basics**: regression, logistic, k-NN

- **Linear regression**: fit a straight line $y = w \cdot x + b$ by least squares (minimise the summed squared errors) to predict a continuous value, e.g. hardness from modulus
- **Logistic regression**: squash the linear score through a sigmoid $\sigma(z) = 1/(1 + e^{-z})$ into a probability $P \in [0, 1]$; predict the class when $P > 0.5$
- **k-NN**: no training; label a new indent by majority vote of its k nearest neighbours (small k overfits noise, large k oversmooths)

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

19

19

Clustering depth: **GMM** and choosing k

GMM: soft clustering

- Models the data as a **mixture of Gaussians**, $p(x) = \sum \pi_k N(x | \mu_k, \Sigma_k)$: a weighted sum of bell curves, one per phase
- Gives each indent a **posterior probability** of belonging to every phase, not a hard label

Reading uncertainty

- The posterior splits near **phase boundaries** where responses overlap: it shows where the model is unsure

Choosing k

- **Silhouette** = $(b-a)/\max(a,b)$: how much tighter a point sits in its own cluster (a) than the nearest other (b); its peak sets k (here $k = 3$)

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

20

20

Density clustering & bagging vs **boosting**

Decision tree

- A flowchart of **yes/no splits** on the features (is modulus > 200 GPa?); each path ends at a leaf that assigns a phase

Random forest (bagging)

- Grow **many trees**, each on a bootstrap resample and a random subset of features; **average their votes** so independent errors cancel (low variance)

Boosting (XGBoost)

- Add trees **in sequence**, each correcting the last one's errors (low bias)

HDBSCAN (clustering)

- Groups points in **dense regions**; no preset k, sparse points labelled noise (-1)

A decision tree: yes/no splits down to a leaf. A random forest = many such trees, majority vote.

XGBoost: Gradient Boosted Decision Trees

- XGBoost (Extreme Gradient Boosting) is a high-performance implementation of **gradient-boosted decision trees**, optimized for speed, accuracy, and interpretability.
- Build an ensemble of **weak learners** (decision trees) where each new tree **corrects the residuals** (errors) of the previous ensemble.

The rare-phase problem: SMOTE

The rare-phase trap

- A minority phase is a few percent of indents, so a model can score high **accuracy** while never predicting it: judge by **recall** (fraction of the rare class actually caught), not accuracy

SMOTE

- Synthetic Minority Over-sampling**: create new minority examples on the line between a real one and a neighbour, $x_{\text{new}} = x_i + \lambda(x_{\text{nn}} - x_i)$, $\lambda \in [0, 1]$
- Adds variety instead of duplicating rows, so the classifier sees a balanced training set

Here

- Used in the meteorite label refinement (XGBoost + SMOTE)

SMOTE — synthesise rare-class points

Autoencoders and the latent space

Autoencoder: a network trained to reproduce its input through a narrow **bottleneck**, so it must compress each load-depth curve into a few numbers (the **latent space**) and rebuild it. Similar curves land close together in that space, giving an unsupervised map that needs no labels.

Trusting a model: **evaluation** & validation

Cross-validation

- Rotate the held-out fold K times; report a **mean $\pm$ std**, not one lucky split

Confusion matrix (left)

- Rows = true phase, columns = predicted: the **diagonal is correct**, off-diagonal are the mistakes

Precision / recall / F1

- **Precision**: of those called X, how many are X = $TP/(TP+FP)$
- **Recall** (true-positive rate): of the real X, how many caught = $TP/(TP+FN)$
- **F1**: harmonic mean of precision and recall

ROC / AUC

- ROC: **true-positive rate vs false-positive rate** ($FP/(FP+TN)$) as the threshold slides
- **AUC**: area under the curve = 1 perfect, 0.5 chance

Detecting anomalies: **pop-in events**

Pop-ins

- Sudden **displacement bursts** on the load-depth curve, the signature of dislocation nucleation or film/crack events under the tip

Why it matters

- They break the smooth Oliver-Pharr fit, so an undetected pop-in corrupts the extracted **H** and **E_r** across 10^5 auto-fitted curves

CNN detection

- **Convolutional neural network**: slides small learned filters over the curve to detect the local burst pattern, separating typical from anomalous indents (~93%)

How sure is the model?: **uncertainty**

Dropout

- During training, randomly **switch off** a fraction of neurons each pass, so the network cannot over-rely on any one unit (a regulariser against overfitting)

MC-dropout

- Keep dropout **on at prediction** and run the input ~50 times: each pass is a different sub-network, so the **spread** of the outputs is the uncertainty

Reading it

- σ peaks at grain boundaries and phase mixtures, flagging where to measure next

27

A gentle warm-up: teaching a **CNN** to read digits

Before turning to nanoindentation, it helps to watch a convolutional neural network (CNN) work on a problem everyone recognises: reading handwritten digits. MNIST is the classic benchmark: 70,000 small greyscale images of the numbers 0–9.

A CNN slides small learnable filters across each image to pick out strokes and curves, stacks them into higher-level shapes, and outputs a probability for each digit. After only a couple of minutes of training on a laptop CPU it reaches about **99% accuracy**: the confusion matrix is almost perfectly diagonal, so nearly every digit is read correctly.

The very same machinery: filters, pooling, a probability output: is what later reads indentation curves and micrographs. MNIST is just the friendliest place to meet it.

► [Run it: notebook 10](#)
scan or click · Colab, no install

28

Two ways to feed a CNN: the **raw curve** itself (1-D)

A load-depth curve is just a sequence of numbers, so a CNN can read it **directly**: a one-dimensional filter slides along the curve looking for characteristic shapes: the loading slope, the unloading knee, a pop-in step.

This is the counterpart to notebook 04, which first turned the curve into a 2-D image. The 1-D version keeps the true **magnitude** of load and depth; the image version emphasises **shape** and is scale-invariant. Choosing between them is a real modelling decision, and the tutorial shows both so you can compare.

Trained to tell soft from hard indents, the 1-D CNN reaches about **96% accuracy** (confusion matrix: only 69 of ~2,000 curves misclassified).

► Run it: [notebook 04a](#)
scan or click - Colab, no install

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

29

29

Predicting **numbers**: physics fits and regression

Not every task is classification: sometimes we want a continuous number. Two complementary routes are shown. A **physics model**: Kick's law $P = C \cdot h^n$ is fitted to the curve (left), recovering interpretable constants (here $C = 2.5 \times 10^{-4}$ and exponent $n = 1.89 \approx 2$, the value expected for a self-similar indenter). A **data-driven model**: a random-forest regressor predicts hardness from simple curve descriptors and reaches $R^2 = 0.97$ against the measurements (parity plot). The bar chart shows what it relies on: the maximum load $P_{\max}$ dominates: so the prediction is interpretable, not a black box.

► Run it: [notebook 12](#)
scan or click - Colab, no install

Machine Learning for Nanoindentation - Edoardo Rossi - MecaNano WG4 – Tutorial 1

31

30

Labelling **every pixel**: U-Net image segmentation

Clustering labels each indent; **segmentation labels each pixel** of an image. A U-Net is a convolutional network shaped like a U: it compresses the image to grasp context, then expands it back to full resolution, so it can outline phases or defects precisely. It is needed because the two phases **overlap in brightness** (histogram): a simple grey-level threshold fails, but the network learns their texture and shape. Trained on a handful of annotated micrographs it predicts masks that match the ground truth, and the predicted phase fraction falls on the parity line: the route from raw images to quantitative phase maps.

► [Run it: notebook 15](#)
scan or click - Colab, no install

32

31

Finding and counting features: **object detection**

illustrative detections (box · class · confidence)

Some questions are not 'what phase is this?' but '**where are the features, and how many?**': counting precipitates, pores or etch-pits across a micrograph.

Object-detection networks such as **YOLO** ('You Only Look Once') answer this in a single pass: they draw a bounding box around each feature and attach a class and a confidence score. Because it localises and counts automatically, it replaces hours of manual annotation and gives reproducible statistics: density, size distribution, spatial clustering: over large images.

Shown here on synthetic micrographs so it runs anywhere; the same network retrain on real defect images. It is the most advanced, optional tool in the set.

35

34

Why correlative characterization?

- Combines mechanical maps (nanoindentation) with compositional and structural maps (EDS, EBSD)
- Purpose: link local mechanical properties to phase, composition, and crystal orientation
- Applied in diverse systems: alloys, composites, natural materials, meteorites

Machine Learning

7/15/2026

Edoardo Rossi - MecaNano WG4 – Tutorial 1

35

35

How can I use this knowledge for materials characterization?

Li-ion cathodes

- Only co-registered mechanical, structural, and chemical information can reveal the true degradation drivers.

<https://doi.org/10.1016/j.joule.2022.04.001>

Ion-irradiated materials

- local mechanical response with defect/chemistry maps is required to build and validate hardening and embrittlement models.

38

38

High-speed (high-resolution) nanoindentation

➤ What does it take to do high-speed nanoindentation?

- Compression in time (normal way, but do it fast)
- One full load-unload cycle and movement to the next position can be completed in less than one second

➤ Why should you do it?

- High-throughput data (statistics)
- Probe heterogeneity (**mapping**)
- More likely to be accurate (thermal transients, vibrations, environment). Less influence of the environment.

7/15/2026

Edoardo Rossi - MecaNano WG4 – Tutorial 1

41

41

Traditional correlative characterization: EPMA, EBSD, Nanoindentation

- Combined EBSD, EPMA, and nanoindentation reveal the role of:
 - Crystal orientation on modulus and hardness.
 - Oxygen content on mechanical strengthening.
- Reduced modulus and hardness show orientation-dependent trends.
- Data correlation allows separating anisotropy effects from compositional variations.
- Approach applicable to high-throughput studies of alloy development.

Commercially pure titanium

Correlated nanoindentation, EBSD, and EPMA on commercially pure titanium. Mechanical properties (modulus and hardness) are linked to grain orientation and oxygen concentration.

The curve becomes an **image**: Gramian Angular Field

Gramian Angular Field image

Curve → image rescale the curve to angles, then encode pairwise sums as a 2-D map (GAF).

Why a CNN can now read the whole load–depth response: the basis of the WC–Co classifier.

Caveat the GAF is scale-invariant: it sees shape, not magnitude · notebook 04.

Laia Ortiz, Edoardo Rossi, Claus Trost et al. (unpublished)

60

Probabilistic phase maps **agree**

The hardness and modulus maps, and the RF and CNN probability maps, all **track each other** (panel f): two independent classifiers reaching the same answer is strong evidence the maps are real, not artefacts.

Because the estimate is statistical, **binder pockets finer than the indent spacing** survive as elevated binder probability rather than being averaged away.

Laia Ortiz, Edoardo Rossi, Claus Trost et al. (unpublished)

How sure is the model? Prediction **uncertainty**

Prediction uncertainty peaks at $P(WC) \approx 0.5$ (the genuinely mixed indents where WC and binder overlap) and collapses toward pure WC or pure binder. The model does not just classify; it reports where to trust the map and where the microstructure itself is ambiguous.

Laia Ortiz, Edoardo Rossi, Claus Trost et al. (unpublished)

Validation against SEM ground truth

Against SEM segmentation, ROC-AUC = **0.92 (hardness)**, **0.78 (PCA+RF)**, **0.79 (CNN)**. Disagreement concentrates at WC/binder boundaries: the same mixed indents flagged as uncertain, so errors are honest and interpretable.

How can we identify automatically? ML clustering

➤ Multi-scale clustering combining nanoindentation (H, E) and micropillar compression (σ_y , $\sigma_{\max}/\sigma_y$) with derived ratios (H/E, H^3/E^2): 6 features, z-score standardised

➤ Ward hierarchical clustering with silhouette-driven k selection; k=4 optimal (silhouette = 0.41, perfect Ward–KMeans agreement ARI = 1.0)

➤ **4 mechanically distinct regions plus 1 outlier region**

Edoardo Rossi et al. (unpublished)

Towards Operando and Fully Automated Mapping

Operando: measuring the mechanical properties of materials while they are exposed to service-like conditions during the experiment.

- Operando mapping extends high-speed nanoindentation to temperature- and environment-controlled experiments.
- Simultaneous correlation with compositional mapping (EDS) enables:
 - Phase boundary tracking
 - Diffusion profile characterization
- Real-time ML-driven adaptive mapping adjusts resolution and sampling dynamically.
- Towards fully autonomous mechanical microscopy platforms.

Ni-Mo diffusion couple at temperature.
